

## What does a **Version Control System** do?

- Track source code
  - Maintain code history, integrity, atomic change...
- Coordinate distributed development
  - branch, merge conflicts, tag...

## VCS Work Flow Categories

- Centralized: **VSS**, **CVS**, **SVN**
- Distributed<sup>1</sup>: **BitKeeper**, **git**, **mercurial**...

## Why git is better than X (SVN, CVS, ...)

- git is super fast
- Full repository clone
- Local history: no need to connect to servers when viewing the revision history
- Cheap branch and easy merge
- **github**: social coding<sup>2</sup>
- Other things: tidy working directory, better compression, multi work flow support, ...

## General Advice on Learning git

- Try git and github
- Most graphical tool/plugin<sup>3</sup> *SUCK*. Please use the command-line git.
- Read git's prompts, run **git help** to get help.
- Find “how-to” on Google, StackOverflow, git book.

---

<sup>1</sup>Distributed VCSs support centralized work flow too.

<sup>2</sup>**bitbucket**, **Google Code** support git too, but github in no doubt has more *fun*.

<sup>3</sup>**tortoisegit**, **gitk**, **EGit**, **Snow Octocat**... But please, oh please use the command-line tool.

Figure 1: VCS general work flow

## Rules of Thumb for git

- “A clear development flow is worth thousands of VCSs.”
- Modular design, avoid simultaneous source file editing by different members.
- Head version at trunk is always ready to deploy.
- Modification is made on branches, then merged into trunk.
- Stay on your own branch.
- Write comment to each commit.

## To get started, I will...

- Illustrate git’s various work flows.
- Explain the most frequently used git commands.
- Give exercises for self check. Some of the exercises require github access.

## git’s stand-alone work flow

- You can use git on a stand-alone computer and easily integrate the code into a more sophisticated work flow (distributed or centralized) at a later time.

## git’s distributed work flow

- Every collaborator keeps a full clone of the repository.
- All repositories are peers.
- Repositories are not necessarily consistent at all time. Use push/pull to exchange changes when necessary.

Figure 2: gitalone

Figure 3: gitdvcs

## git's emulation to the centralized work flow (RECOMMENDED)

- It's **emulation**, not *real*.
- The statement, “all repositories are peers.”, still holds.
- We pretend that we see the central repo only, unaware of each other's peer repo.

Figure 4: gitcent

## Set up git

- Please follow github's nice tutorials to set up<sup>4</sup> git on [Windows](#), [Linux](#) or [Mac](#).

---

<sup>4</sup>The email you fill in when signing up is used for web login and password reset only. github uses SSH keys for git authentication. Try to clarify the following *pass phrases*: your email account's pass phrase, your github account's pass phrase, and the pass phrase to access your SSH private key.

- **Must-known things about SSH keys:** private key, public key, the pass phrase to access the private key, key fingerprint.
- Don't forget to set `user.name` and `user.email`<sup>5</sup> before your very first git commit.

## git command

- help
- init
- status
- add
- commit
- diff
- tag
- Working with branch
- Working with remotes
- submodule
- Oh, there is a conflict!!!
- “Time Machine”

## help: Get help

`git help COMMAND` Get help from git.

- `git help add`
- `git help commit`
- ...

---

<sup>5</sup>Username and emails in git's configuration are for identification purpose only, not for sending emails. It is highly recommended that the email in git and SSH keeps the same.

## init: Initialize a local git repo for your project

`init` command will create a `.git` dir on the top level of your project.

1. `cd YOUR_PROJ_DIR`
2. `git init .`

## status: Show the status of your repo

`git status`

- `status` tells you how to **UNDO** the last operation on git
- **File status:** untracked, unstaged, staged (indexed), committed<sup>6</sup>

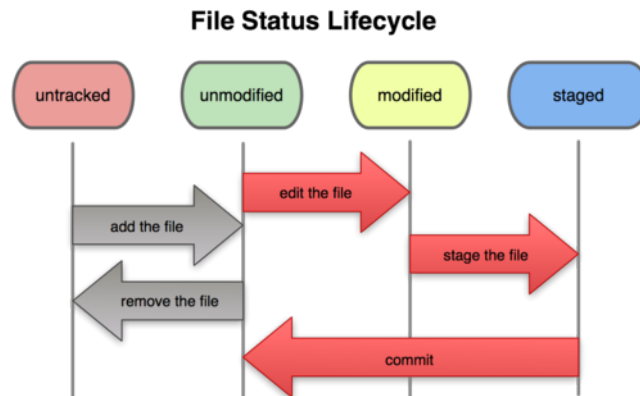

Figure 5: gitlifecyle

## add: A multi-function git command

`git add FILES_OR_DIR`

- For untracked files: *add* them to git's control
- For unstaged changes: *add* them to the staged area
- For conflicted files: *add* marks them as "resolved"

---

<sup>6</sup>The *committed* status simply displays nothing when running `git status`.

## .gitignore: Ignore files

- Specify file types to ignore in .gitignore (a normal text file)
  - .tmp (Ignore all \*.tmp files)
  - .bak (Ignore all \*.bak files)
- git has an internal .gitignore. You can ask git NOT to ignore some file types in .gitignore
  - !\*.o (*Don't* ignore \*.o files)
- git help gitignore

## commit: Store the status (snapshot) permanently

- git commit -m "YOUR\_COMMENT"
  - git commit Stores the STAGED changes only
  - git commit -a Stores all the STAGED and UNSTAGED changes.
- Please write comment for each of your commit.
- Each commit is identified by a **UNIQUE** SHA-1 ID of 40 ASCII characters.

```
commit dd5f924c40096b9cda27ffd1cfd1205822ab3c70
Author: Github Support <me@github.com>
Date:   Sun Apr 1 19:38:37 2012 +0800
```

Restart the git-tutorial project.

## diff: Find differences

- git diff
  - changes between the staged and working files
- git diff --staged
  - changes between the HEAD and the staged files
- git diff HEAD
  - changes between the HEAD and the working files
- git diff COMMIT\_ID COMMIT\_ID
  - changes between two commits

## tag: A milestone version

- `git tag`
  - See all the tag
- `git show TAG_NAME`
  - See a tag in detail
- `git tag TAG_NAME`
  - Add a “lightweight” tag
- `git tag -a TAG_NAME -M YOUR_COMMENT`
  - Add an annotated tag
- `git tag -d TAG_NAME`
  - Delete a tag

## Submodule: Integrate multi git repos

- `git help submodule`
- [Repo in Repo](#)
- Manage other repos as “submodules” in your project

## Working with branch: branch, checkout, merge

A branch-based development flow:

1. Create a branch
2. Switch to the newly-created branch
3. Modify and commit on the branch
4. Merge branch’s changes into trunk.

## Working with branch: branch, checkout, merge

- `git branch` See all the branches
- `git branch BRANCH_NAME` Create a branch
- `git branch -d BRANCH_NAME` Delete a branch
- `git branch -D BRANCH_NAME` Force delete a branch

## Working with branch: branch, checkout, merge

- `git checkout BRANCH_NAME` Switch to a branch. The working files will change.<sup>7</sup>
- `git checkout -f BRANCH_NAME` Force switch to a branch
- `git checkout master` Go back to trunk, named *master* in git.
- `git checkout -b BRANCH_NAME` Create a branch then switch to it.

## Working with branch: branch, checkout, merge

- `git merge BRANCH_A BRANCH_B` Merge branch\_a's and branch\_b's changes into *current* branch
- `git checkout master, git merge master BRANCH_NAME` Merge changes into trunk, the master branch.

## Working with remotes: clone, remote, push, pull

- `git clone REPO_URL` Full clone of a repo.
- URL can be in forms of local dir (`~/proj`), git (`git://xxx`), SSH (`ssh://xxx`), https (`http://xxx`)...

## Working with remotes: clone, *remote*, push, pull

- `remote` Manages the set of tracked repositories.<sup>8</sup>

---

<sup>7</sup>Don't confuse git's term **checkout** here with Subversion's checkout.

<sup>8</sup>Remote repos in git are just references or pointers, so you lose or gain *nothing* when adding or removing a remote repo.

- `git remote`
  - Show all the tracked repositories.
- `git remote show REPO_NAME`
  - Show the repo's details.
- `git remote add REPO_NAME REPO_URL`
  - Add a remote repo to tracked list.
- `git remote -d REPO_NAME`
  - Remove a remote repo from the tracked list.
- `git remote rename REPO_OLD REPO_NEW`
  - Rename a repo.

## Working with remotes: clone, remote, push, pull

- `git pull REPO_NAME REMO_BRANCH`
  - Merge remote branch's changes into current branch.
- `git push REPO_NAME REMO_BRANCH`
  - Push current branch's changes to the remote branch.
- `git push REPO_NAME :REMO_BRANCH`
  - Delete a remote branch.

## Oh, there is a conflict!!!

- A conflict looks like:

```
<<<<<< HEAD:index.html <div id="footer">contact : email.support@github.com</div>
===== <div id="footer"> please contact us at support@github.com
</div> >>>>>> iss53:index.html
```

- Conflicts arise when git cannot automatically merge changes at merge or pull operations.
- Don't panic. Conflicts are no big deal, sometimes even inevitable.
- What you should do: merge the conflicts, mark the files as "resolved", then commit the changes.

## Working with conflicts: merge, resolve, commit

1. You have to edit the conflicted files, merge conflicts MANUALLY. `diff` command may help you.
2. `git add CONFLICT_FILES` Mark the file as resolved.
3. `git commit -m "YOUR_COMM"` Commit changes to the repo.

## “Time Machine”: stash, checkout

`stash` saves your temporary work and resets the files to HEAD version. You can handle some emergency fix first then continue to hack at a latter time.

1. `git stash`
  - Save the temp changes.
2. `git stash list`
  - Check the stash list.
3. EDIT and COMMIT your emergency fix.
4. `git stash pop`
  - Continue to hack

## “Time Machine”: stash, checkout

`checkout` enable you to go backward and forward in the revision history.

1. `git checkout COMMITID_OR_TAGNAME`<sup>9</sup>
  - Time Machine starts up.
2. You are on a `unnamed` branch with file status dating back. Do anything you want.
3. `git checkout master`
  - Come back to master.

---

<sup>9</sup>The full commit ID is 40 characters long. But you may type a short prefix (like 4~6 characters) to refer a commit uniquely.

## Exercise 1: Set up git environment

1. Set up git on your computer, and sign up a github account.
2. Initialize a local project as git repo, make your first git.
3. Email your SSH public key file as an attachment to [me](#). Name your pubkey file after “YOUR@EMAIL.pub”, e.g., you should rename your `id_rsa.pub` to `xxx@sjtu.edu.cn.pub` and send it to me.

## Exercise 2: git basics

Be familiar with `status`, `add`, `commit`, `diff`, `tag`.

## Exercise 3: Branch-based development

1. Create a branch.
2. Checkout to that branch.
3. Merge the changes into trunk (master).
4. Delete the branch.

## Exercise 4: Be social on github

1. Follow [me](#) on github.<sup>10</sup>
2. I will add you as a collaborator. Please wait for my message on github before preceeding to next setp.
3. Clone the [GitForBeginners](#) project with Read+Write access.
4. Write something into the `README.txt` (DON'T destroy the description header). `add`, `commit`, `pull`, `push`.

---

<sup>10</sup>Please feel free to unfollow me when finishing all the required exercises.

## Exercise 5: Manage remotes

1. You clone the remote repo `GitForBeginners` on github. Try `git remote`.
2. Copy the `REPO_URL` to somewhere else.
3. Delete the remote repo.<sup>11</sup>
4. Add the remote repo `REPO_URL` with a name you prefer, such as `myrepo`.
5. Rename the remote repo to its original name – `origin`.

## Exercise 6: Remote branch

1. Create a local branch with your full name, such as `zhangsan`.
2. Write something into `README.txt` on the branch. `add`, `commit`, `pull`, `push` to the remote branch.
3. Leave the branch on github as a mark of “I finish the homework”. Please recreate the the remote branch if you’ve tried the *delete remote branch* command.

## Exercise 7: Handle conflicts

1. Clone `GitForBeginners` twice into two seperate projects, namely `proj_A` and `proj_B`.
2. In `proj_A`, modify `README.txt`. `add`, `commit`, `pull`, `push`
3. In `proj_B`, modify the *SAME* lines of `README.txt` as you do in `proj_A`. `add`, `commit`, `pull`
4. A *conflict* towards `README.txt` arises in `proj_B`.
5. Resolve the conflict, then `add`, `comit`, `pull`, `push` to github.

## Exercise 8: Time Machine

Use `stash`, `checkout` to do time travle.

---

<sup>11</sup>Don’t worry. It is just a reference.
